

David's story of improvement after autism and focal epilepsy via Umbilical Cord Blood Treatment in 2020

David was diagnosed in his very young childhood with moderate form of Autism Spectrum Disorder (ASD) and focal epilepsy.

At the age of 10 months, he started to present typical symptoms such as delayed language development, movement and learning skills, as well as hyperactive, impulsive, and inattentive behavior with severe sleeping problems. In addition, the diagnose of focal epilepsy was given.

Although receiving physiotherapy and ABA (Applied Behavior Analysis) therapy on a daily base, David showed almost no improvements over the next two years; beside using the words "Mom", "Dad,", and "Ready", he nearly showed no correspondence or social interactions with absence of visual contacts.

In October 2020 with David being 3 years of age, we (parents) contacted CBC Health and together with the whole team led by head physician Dr. Nils Thoennissen we set all the details to start near-term intravenous treatment with allogeneic, ABO-matched umbilical cord blood.

Only a few days after the well-tolerated treatment, David was able to sleep for 10 hours without interruption. We were extremely excited and could not believe this success. Within a year after the treatment, David has made significant progress in his developmental skills: he now is able to go to kindergarten, to take swimming lessons, and speech therapy is noticeably improving his language.

The cord blood treatment helped David to be present, to have eye contact, and to observe the things and people around him.

Being a real success for our son David, we have every confidence to go for a second treatment with CBC Health umbilical cord blood to further boosting his developmental skills.

"Thank you from the bottom of our heart to the whole team at CBC Health led by head physician Dr. Nils Thoennissen!"
